

Identifiers: What is it and how to create it

An identifier is an image that pyautogui tries to locate in your screen and move the mouse to it in order to complete a flow. It's important that the RPA can locate all the identifiers to work well. Here is an example of how it looks like:

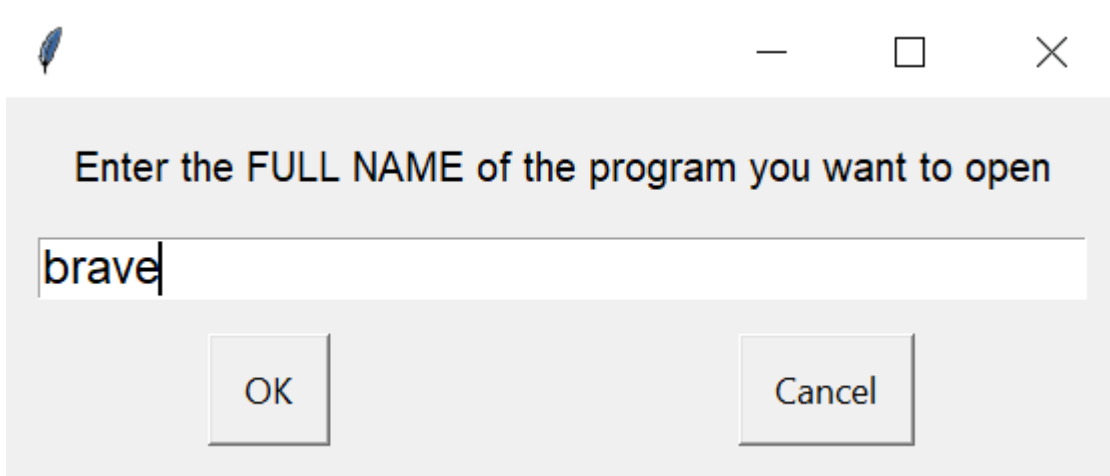

Word identifier

All the identifiers are located in `app\src\opening_programs\identifiers`

Here is an example of a use and installation of an identifier:

In this case I'm trying to open "Brave"

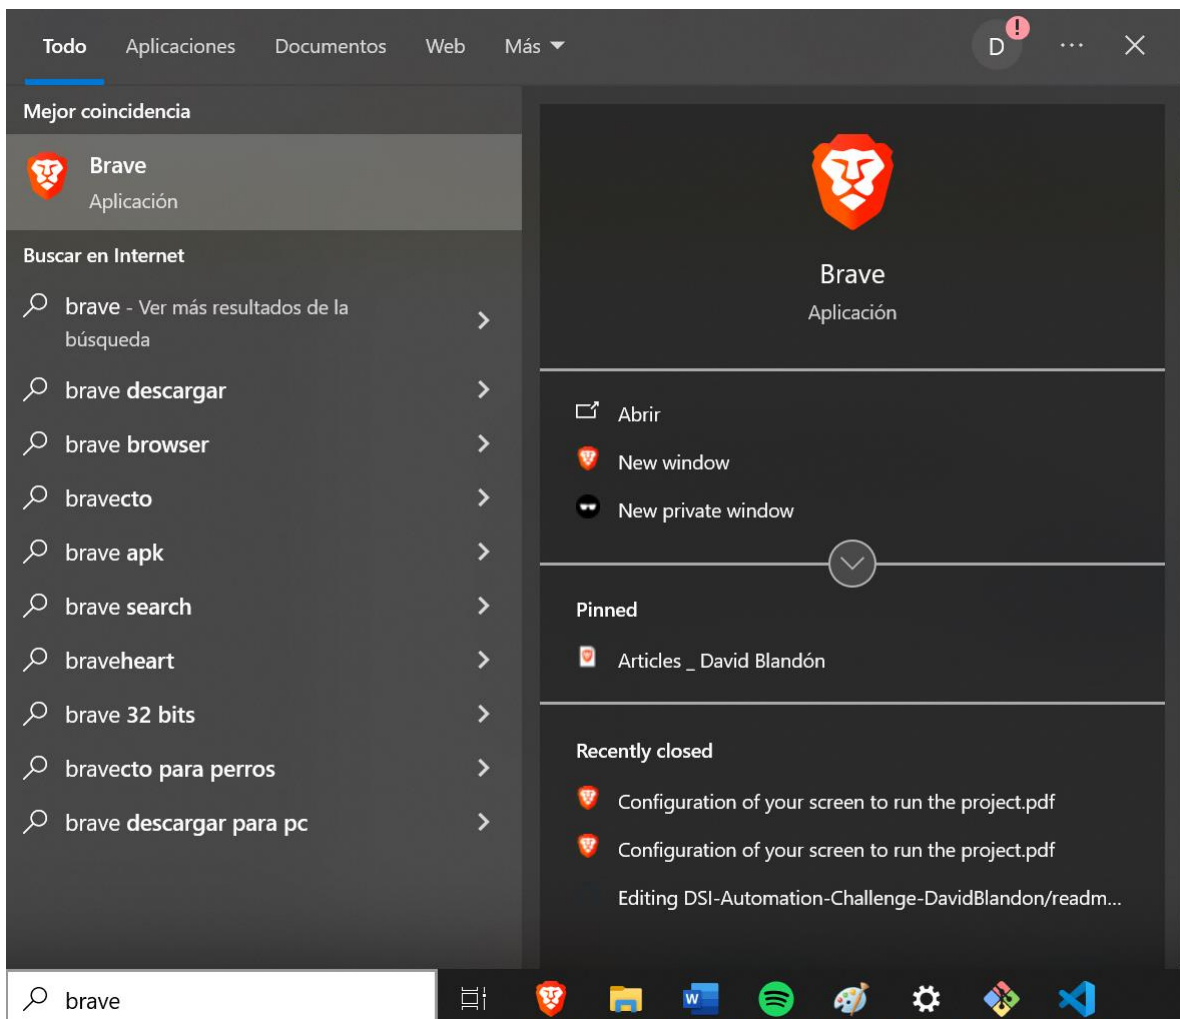

But since I do not have an identifier for it, the following error will be prompted

The identifier was not found, please create one
Check the documentation of identifiers for more information

Aceptar

So, we will create one. We search brave in our file's browser

Then screenshot the section of the logo

And save it in the route `app\src\opening_programs\identifiers` as “brave.png” in lower case.

Now we can open Brave with the RPA.

Note: If when you run some flow you are having some issue finding some identifier on your screen, I recommend creating your own identifiers. Based on the resolution, the brightness, and the colors there can be some troubles.
